Free Download Motorola Iden Cns Unlock Ver 7.0.rar . Free Download Motorola Iden Cns Unlock Ver 7.0.rarQ: MobileFirst : How to run/debug a standalone packaged application As I've been working in cordova and developing client-side applications, there is a good chance to debug my application in the emulator or a device. How can I do the same with a MobileFirst application? When launching the app in the MobileFirst Development Server, is it possible to run/debug it in the runtime or the debugger on a device? I don't find anything similar in the documentation, nor i don't know how to configure the DevServer to use my remote device on the fly. A: I've been doing this for a couple of months now and I can tell you that it's not easy, but you can get it working. First, you will need to deploy your application to a test (development) server where the application can run and you can debug it (in this case I use WAS Liberty). Second, you will need to create a new runtime on the server, which will be available for the development server (FTP or deploy a file). In this case I created a special application called "AppDev" where the application can be executed, debugged and tested. After that, you need to update the -server.xml file in the deployRoot folder to add new configs in order to use new runtime. Third, after that, you will need to make sure that you can deploy your application to this new runtime; if the process is successful, you can start the development server on your device where your new application can be tested. Depending of your use case, there are other tasks, for example: You will need to map the ROOT context in order to avoid that your application will use the old ROOT context and generate old errors. You will need to install the mobileFirst SDKs on the new runtime. The trickiest part will be to make the correct configuration, but there are some great tutorials about how to do that. The link of one of the best tutorial, called "Mobile First Developer's Guide" is: 3ef4e8ef8d
