The aim of this study was to assess the feasibility and benefits of a laparoscopic repair of gastrointestinal (GI) perforations. The medical records of patients treated laparoscopically for various etiologies of perforation were reviewed retrospectively and followed prospectively. Patient demographics, perforation site, and size, and duration of perforation were determined. Patient outcome, complications, and duration of surgery, analgesic requirements, and hospital stay were noted. From 1992 to 1995, 33 of 34 patients underwent laparoscopic repair of GI perforation. One patient underwent conversion to open laparotomy for presumed perforation of the colon. Patients averaged 46 years of age and had a mean Injury Severity Score of 12.2. The most common perforation site was the duodenum (n = 17). In eight patients, acute emphysema or pneumoperitoneum was initially observed. There were six enterotomies, two gastric wall disruptions, one gastric perforation, two duodenal perforations, two jejunal perforations, and one sigmoid perforation. Twenty-five patients (76%) had partial repair. One patient had an intrathoracic esophageal tear and was converted to open repair. Complications occurred in 21 patients (64%). There were five (15%) conversions to laparotomy. Mean operating time was 125 minutes. The mean duration of analgesia was 3.1 days, and mean hospital stay was 7.3 days. Only one patient 4bc0debe42
